

Multi-tenancy and Virtualization

Policy management for different domains from a central console will make resource usage and disk usage to be lowered and management to be more effective. In big corporations and MSSPs there are different divisions, subsidiaries or companies having separate system, network and needs. Multi-domain management is an important feature for these companies. Making policy management centrally can also improve security by centralizing access control and monitoring for all domains.

Multi-tenancy, virtualization or both?

Opinnate brings multi-tenancy and virtualization together

In its unique feature domains be separated from each other like virtualization on firewalls. Separate admin accounts, separate networks, different policies and task lists will be possible as it should be. Different authorization levels and admin users configured to reach different virtualized instance possibility for multi-tenancy purposes.

Virtual NSPM solution like virtual firewall

Opinnate makes it possible to manage different companies from a single console. It is an easy task to connect each virtual area and start working there if you have the authorization to manage that virtual area. Analysis, optimization of the rules and policy change automation will be the activity specific to that virtual area.

Benefits

- Multi-tenancy
- Virtualization of domains
- Management efficiency
- Effort gain
- Lower disk usage
- Lower CPU, RAM usage
- Lower TCO

Automation in virtualization level

It becomes possible to separate tasks

Each virtual area is a separate instance and this makes activities to be done on each of them isolated from others. Each company may be using different service desk systems and for each of them different integrations to be made. When an automation task is taking place on one of the virtual areas, on the others optimization tasks or just the analysis process may be going on. It may also be possible to manage these virtual areas in different package levels lite, standard and enterprise.
